Purpose and Overview of the Study:

This study was commissioned by Kahler Communications, Inc., Little Rock, AR for the purpose of reviewing what support, if any, there was to be found of Dr. Kahler's theory with respect to Phase progression/regression/statics and, additionally, examine the consistency of described personality profiles of individuals. These objectives were to be accomplished via the comparison of test scores of a number of persons who had taken the "inventory" at least twice. "Inventory", in this study refers to the Personality Pattern Inventory (hereafter PPI) developed, copyrighted, trademarked and distributed by Dr. Taibi Kahler and Kahler Communications, Inc. The cases (individual's PPI results) used in this study were drawn from Kahler Communications files in a search for all individuals who had submitted valid PPI "answer sheets" on at least two occasions within the six (6) year period ending February, 1990. Restated, the objectives of this study were:

- o Determine if there was evidence in support of Dr. Kahler's theory with respect to Phase change;
- o and, examine the consistency of the lest instrument (the PPI) in specification of "personality patterns".

The procedure adopted to address these two objectives was to specify a number of statements (so called "null hypothesis") and then to test the numerical case evidence for the purpose of accepting or rejecting these "hypotheses". Some of the major hypotheses were:

- Any differences found between Phase Type and Kahler's theory are due to random fluctuations from sampling.
- Time interval between "testing" sessions is not a predictor of current indicated Phase Type.
- "Questionable Validity" alerts (printed statements on the Results Form) are not predictors of current indicated Phase Type.
- Changes in the specific order of sub-measures do not indicate variance from Phase Theory.
- o Raw sub-measure (test) scores are consistent.

There will be detailed discussion of the tests and findings related to each of the above hypothesis in the "Discussion of Findings". In this current section only a statement of the major results will be presented.

85.2% of the 204 cases examined (408 test sessions) were found to conform to Dr. Kahler's theory—these results are accurate $\pm/-3\%$ at one (1) Standard Error or $\pm/-6\%$ at two (2) Standard Error. In other words, 66.7% of the time we can be confident that the true results are within $\pm/-3\%$ of 85.2% or 95% of the time, within $\pm/-6\%$ of 85.2%. Hence considerable confidence can be placed

upon Kahler's theory in its ability to predict changes in behavior. Corollary to the previous proof is the evidence that "time interval" is not predictive of Phase. This paper is not a discussion of psychological theory, if for no other reason, the writer is not qualified or educated sufficiently to discuss such; however, within the realm of the statistical tests performed and, also, within the realm of logic, if time were a major predictor then Kahler's theory would have weakened foundations. That is, if time was a valid predictor it would discredit the theory which states that. Phase change is based upon "need", long-term distress and/or short-term eastress, as explained to the writer by Dr. Kahler (and this is as close to psychological theory as the writer is comfortable with) Put another way, if Phase could be explained by time it would negate the effects of life experiences; this is to say, if the passage of time is a controling vaiable, then all subjects would exhibit correlated and similar changes in a given time span. This introduces a dichotomy, either the PPI measures changes in Phase types which are dependent upon the expiration of time or the Inventory measures changes in Phase types which are influenced by other factors. Therefore, it was entirely possible for the writer to test the theory without either knowledge or understanding of the theory. Time explained changes in Phase Type - or not. Specifically, Kahler's Phase types were treated as classifying dependent variables and the time interval between tests was treated as an independent variable. A model encompassing these attributes was analyzed using a multivariate least squares computer program (MGLH of the SYSTAT System copyright (c) 1986 SYSTAT, Inc.). Coefficients of the time variable ranged between -0.007 and 0.006; none of which could be considered significant, regardless of the respective F-Statistics or probabilities.

"Questionable Validity" alerts relate to psychological interpretation by definition. These were quickly dismissed as having any Phase type predictive capability. Changes in the specific order of submeasures indicates volatile "personalities" – which is to say that certain cases exhibited re-orderings in the "pattern" of Phases. Explanation of these alterations calls for a psychological statement: such statements can only, and properly, be issued by Dr. Kahler. This re-ordering did not significantly reduce the "hits" of predicted phase type. Theory is upheld. The last examination performed was the consistency of sub-measure scores. This test was included as an additional look at the test instrument as a measuring device. Some variation was expected – but such variation was anticipated to be of limited range. In fact, sub-measure scores were found to be very consistent – 5 of 6 sub-measures correlated at the 68.6% or higher level; 4 of 6 sub-measures correlated at 80.8% or higher.

Therefore, the PPI:

- o 1) effectively measures change,
- o 2) is consistent in description of personality patterns;
- o 3) is not controlled by time;

and

• 4) is essentially accurate in predicting behavior patterns.

Mclhodology:

The methodology employed in this study was reasonably straight forward:

- . 1) files were reviewed to identify test subjects which had taken the PPI, at least twice, in a controlled environment;
- the identified cases were further screened to insure that each test taken was of the same "version" or revision;
- cases, screened as per the above, were extracted to paper and identified with a case number;
- selected data from these paper records were input to a computer data base (Please see Appendix A for details of data elements in the data base);
- 5) several statistical tests and other data analysis were specified;
- computer instructions were issued to extract data elements in the various forms required by the several tests;
- actual statistical tests and other analysis were performed;

and

8) results are reported in this paper.

Specific statistical tests and other analysis are reported in the section titled "Discussion of Findings".

Unless otherwise noted, all included statistics and analysis utilized "raw scores". This current study did not have as one of its objectives the analysis of test result reporting format; nor is it within the expertise of the writer to analyze psychological interpretations contained in result reports. This does not imply that there is/are any question(s) regarding either of these two (2) subjects — rather, what should be clearly stated is that these areas were not examined. Therefore, it was determined that the use of "raw scores" would preclude any influences from these areas. Not only was this the simplest operational procedure — but it also eliminated a number of exogenous variables. Readers, with a legitimate need to know, may contact Kahler Communications to determine access to raw scores.

Adequacy of Sample:

While there have been more than 40,000 PPI tests administered in the United States, this number does not represent the Universe of concern. Rather, this study is focused upon those subjects that were tested in a controlled environment and, which also, took the test, in this same environment, at least twice. These requirements define the Universe of interest to be populated by 5-6,000 cases. Additional screening for complete data in conjunction with authorization to use private test results resulted in a sample size of 313 cases gross. Data edits for encoding errors, incomplete data and questionable validity "flags" further reduced the sample to 204 cases. This sized sample was judged to be more than adequate – in fact, actual statistical test scores are accurate at the level of $\pm 1/2$ 0 at one (1) Standard Error, and $\pm 1/2$ 1 at two (2) Standard Error.

Discussion of Findings:

The development and implementation of a psychological testing instrument is a dounting task. Untold hours of work are required to develop a theory, identify requisite sub-test, verify predictive capability, structure the instrument for ease and accuracy of administration, create administration and interpretation materials, and to recruit subjects. Regardless of the value, or apparent accuracy, the development work is only half done at this point. The second half of the work needed is the determination of repeatability of test results and adherence to the original theory. This second step can be performed only after a period of time has elapsed; in the case of this study, more than six (6) chronological years. Consequently, given the investment in time and effort, there is little doubt that studies such as this are undertaken exercising the greatest amount of care and caution, lest the investment be wasted.

Before entering the main discussion a few statements are in order. It is beyond the scope of this paper to deliver an exposition of Dr. Kahler's theory; the only references to this theory, in this paper, will be such statements as describe the procedures used for classification. There will be no explanation of the logic of these procedures — if the reader is interested in the psychological underpinnings of the procedures, then he/she is referred to Dr. Kahler or any of his many writings.

All analysis conducted in the development of data and results for this paper were conducted using actual sub-lest scores ("raw" scores). This procedures was employed to minimize bias and possible effects resulting from test result reporting forms and interpretations thereof. Readers with a legitimate interest in obtaining raw scores should contact Kahler Communications.

Finally, the reader is reminded that statistical tests can not prove the truth of anything; the most that a statistical test can do is to, given stated assumptions (hypothesis), indicate the likelihood of the accuracy of a result. Housekeeping out of the way, following begins the main discussion of results of this study.

This study was commissioned to examine the ability of the PPI to consistently, and with predictability, describe either comparable (identical) profiles for subjects or, in the case where the profile indicated a change, adherence of the subsequent profile with theory across the two testing sessions. These two test sessions were conducted at varying interval of time. See below:

Display of Ti	me Intervals	Belween	Testing	Sessions
Period		Count		Percent
0.0 - 0.5 yrs		3		1.47%
05 - 10		18		8 82
10 - 1.5		12		20.59
1.5 - 2.0		32		15,69
2.0 - 2.5		30		14.71
2.5 - 3.0		27		13.23
3.0 - 3.5		20		980
35 - 40		16		7.84
40 - 15		9		4.41
1.5 - 5.0		3		L47
5.0 - 5.5		2		0.98
5.5 - 6.0		2		80.0
Total		201		99.90%
Minimur		days (0.17 ye		
Махіти		days (5.93 ye.		
Mean		313 days (2.2		
S D.	409.	118 days (1.1	2 years)	

The above demonstrates that typical cases were subject to a time interval between test sessions of greater than one (1) years (2.24 years minus one (1) S.D. of 1.12 years yields a minimum standard interval of 1.12 years). In fact, 89.71% of the sample were tested at intervals greater than one (1) year. Specific testing of "memory" was not conducted. Nonetheless, given the complexity of the PPI and the typical interval between testing exceeding one (1) year, a great deal of confidence is placed in the belief that recall of the test questions is not a factor that will harm the following results in any manner.

Discussion which follows will correspond to the order of the stated null hypothesis as presented in the "Purpose and Overview of the Study" section. Therefore, the next topic of discussion is:

 Any differences found between Phase Type and Kahler's theory are due to random fluctuation from sampling.

It is necessary to make a brief statement - this paper is not a discussion of psychological theory. Dr. Kahler provided a "set" of criteria which were used to "classify" test results. Specifically:

Classification Criteria

- 1) If Phase Type remained the same, classify as "Match Theory".
- If Phase Type changed to a Type which was superior, in position, on both tests, classify as "Match Theory".
- 3) If Phase Type changed to be the same as the "Base Type" on the subsequent test, classify as "Match Theory".
- If Phase Type changed to a Type which was subordinate on either or both tests, classify as "Failed Theory".

From the above "criteria" is should be clear to the reader, that statistical analysis could be performed with no expert knowledge of the psychological import of the statements. Examples will make the application of the above clear.

First, in the case where Phase Type remains the same: Kahler uses six (6) classifications for his "Base" and "Phase" categorizations (Persister, Workaholic, Reactor, Rebel, Dreamer and Promoter). If a case result was a profile of the order of:

Persister Workaholic Reactor Rebcl Dreamer Promoter Then both of the following "profiles" would satisfy Criteria #1 or 2:

Persister	Persister
Workaholic	Reaclor
Reactor	Workaholic
Rebel	Rebel
Dreamer	 Dreamer
Promoter	Promoler

Underlined print indicates the current "Phase Type". In a case where "Phase Type", on the subsequent test, was Persister, then Criteria #3 would be met. If indicated Phase Type was Workaholic or Reactor than Criteria #4 would apply.

Thus the first test of the cases submitted was to determine the percent adherence to theory as defined by the Criteria above.

Display	oſ	Res	sults	oſ
Adherer	ice	to	Theo	гу
of Ph	asc	e Cl	nango	,

Description	Count	Percenl
Match Theory	174	85.2%
Fuil Theory	30	14.7
Tolał	204	99.9%

Results as strong as these indicate a high degree of likelihood of the predictive capability of the PPI. While the above results are impressive – this analysis has not gone fare enough. One needs to remember that there are six (6) subtests which comprise a "personality pattern" per the PPI. The case data must be examined for the possibility of random coincidence; specifically, raw scores need to be examined to determine that pattern ordering is not accidental.

Sub-test rank and magnitude was tested through the use of a statistical computer program, MGLH (Multivariate General Linear Hypothesis as distributed by SYSTAT, Inc. (c) (tm)). Within this program a data model was constructed and mulitvariate analysis of variance (MANOVA) performed upon this model. This "model" used the following variables as "dependent variables":

Persister sub-test raw score Workaholic sub-test raw score Reactor sub-test raw score Rebel sub-test raw score Dreamer sub-test raw score Promoter sub-test raw score

and independent variables were.

Constant (offset from the "x" axis)
Test session (1 or 2)
Base Confidence score
Phase Confidence score
False Claiming type (excluding FBU)

Base Type
Phase Type

The outcome of the MANOVA indicated that the hypothesis <u>could not</u> be rejected for any of the variables: specifically (Please see Appendix B for details).

	Results of MANOVA		
Variable	Dgrs of Frdm	F	Prblly
Persister Workaholie Reactor Rebel Dreamer Promoter	5/30) 5/30 5/30 5/30 5/30 5/30	70.637 65 062 93 036 22.636 6.870 4 203	0 0 0 0 0.0 0.0 0 0
Wilks' Lombda Pillor Trace Hotelling—Lawley Trace	30/1546 30/1950 30/1922	20.654 20.241 33.407	0.0 0.0 0.0

These same test were performed with the variables reversed between dependent and independent — no substantial difference was found in any of the "F" statistics. These results are interpreted as support of the hypothesis. In other words, any fluctuations in raw scores or ordering of types is due to sampling, within the assumptions of the model and the tests.

 Time interval between "testing" sessions is not a predictor of current indicated Phase Type.

Results of testing this hypothesis indicate that there is no "learning" influence; nor is there any time affect. Time affect is a crucial topic — if time proved to be a significant variable in predicting Phase Type Kahler's theory could be challenged. That is, theory holds that psychological needs and factors affect Phase, not time. A general linear model similar to the above was constructed and tested to determine the contribution to prediction of Phase arising from "time interval between tests". No significant contribution was found related to the time variable.

Time Variable Contribution to Prediction of Phase Type

Туре	Coefficient
Persister	0 003
Workeliolic	0.002
Reactor	-0 007
Rebel	0.006
Dreamer	-0 003
Promoter	0.004

It is obvious that none of these coefficients are significant; therefore, learning and time can be discounted as having any affect on PPI scores. This is appropriate to Kahler's general theory.

 "Questionable Validity" alerts (printed statements on the Results Form) are not predictors of current indicated Phase Type. This hypothesis was completely upheld. These flags may well have very significant psychological interpretation value; however, these alerts demonstrated no Phase prediction capability whatsoever. There was no real concern that this hypothesis would be rejected - this was examined only for the purpose of ruling out all trivial possibilities. As the numerical results are, also, trivial, such numbers are not reduced to a table - suffice it to say that all probabilities were 0 000 at three decimal places of accuracy.

o Changes in the specific order of submeasures do not indicate variance from Phase Theory.

This is a double-edged sword: if correlations of scores are high and patterns (rankings) consistent, than one might be describing a personality pattern that was static. Is it reasonable to expect some 200+ people, randomly chosen, to exhibit unchanging patterns of personality?— probably not. So the analysis of this hypothesis lies more with expectations than it does with statistical tests...until such point as data of paired-tests is gathered from 2-3,000 subjects (in other words, a very substantial quantity). Of the 85.2% of subject results which matched theory, below is an examination by distribution between: 1) pattern ordering exactly the same between the two test; and 2) theory satisfied, but some reordering of Phase patterns.

Contrast of Stable vs Altered Phase Patterns from Among Cases which Salisfied Kahler's Theory

Туре	Stable	Allered	'folal
Persister	18 9%	63.1%	82.0%
Workaholic	130	73.9	86 9
Reactor	17 6	70.3	87.9
Rebel	12.5	75.0	87.5
Dreamer	50.0	50.0	100
Promoter	-	100	100
Total	17.6	67.G	85.2

Patterns, to a large extent, did show alteration - but, alterations which were within Kahler's theory. What can be said about this table? Intuitively it appears reasonable (that is, based upon a naive interpretation of psychological data). Statistically, it will take many years of data gathering and analysis, such as this current study, before a statistical hypothesis (norm) can be approached. What should be said...is that the general Theory is upheld: whether the patterns are stable or altered. Time and data will provide greater insight on this topic.

o Raw sub-measure (test) scores are consistent.

The MANOV analysis above has already shed some light on this hypothesis; however, it was felt that at least one more look at the sub-test data was warranted. In the current case, it was determined that an examination of the correlations of the various sub-test scores would be useful as a test of the consistency of measurement of the instrument. Does the PPI yield results for subjects which are approximately of similar magnitudes between multiple testing sessions? Yes, it does.

Raw Score Correlations by Kahler Personality Types

Туре	Correlation	Z-Score	Level of Sgnfcnc
Persister	0.98688	2.5126	0.0030
Worksholic	0.98335	2.3924	0.0042
Reactor	0.8076	1.1260	0.0657
Rebel	0.6858	0.8378	0 1002
Dreamer	0.020.0	0.0180	0.2460
Promoter	0.8397	1,2183	0.0556

It would be conclusive if all of the above correlations were very high (greater than, say, 0.80) — there is some suspicion that this would be an overly optimistic expectation. There is one type of slight concern — Rebel, at 0.6858; another type, Dreamer, is of greater concern, at 0.0200. Note — neither of these two scores represents a proven shortcoming of the PPI; rather, given the exhaustive multi-judge work performed in the development of the PPI (see Validity Study), there is reason to believe that the current sample is not indicative for these two types (low numbers of these two Phase Types in sample). In the main, 4 out of 6 high correlations and 5 out of 6 moderate to high correlations does indicate reliable consistency in the results as reported by the PPI. There is no doubt that the Dreamer type correlation will be subject of future study.

Summary:

The PPI is not the "perfect" test, at least as defined within the hypothesis to be tested in this study; however, it is certainly in the grade "A" category. No grounds were found to cause rejection of the PPI — in fact, considerable evidence was discovered which supports the PPI.

This is not a definitive study, rather, it is the initiation of a long series of examinations. Nonetheless, it is very encouraging to find that there is no evidence, to date, which would call for rejection of the PPI. This is not always the case! More importantly, the consistency of scoring on sub-tests and the 85 2% adherence to Phase Theory provide significant support of the viability of the PPI as a predictive instrument of behavioral change.

Every effort has been made to examine and dismiss trite and trivial explanations of results. The PPI clearly demonstrates an ability to discriminate with reliability. Statistically, the sub-measures are valid within definitions and assumptions. Psychological value will have to be determined by those qualified; however, these professionals can, now, go about their analysis without being concerned with the adherence to theory of results...or the consistency of results.
